MODULE 5 : DATABASE

> TOPICS COVERED BASICS OF DATABASE

1. What do you understand By Database

➤ A database is an electronically stored, systematic collection of data. It can contain any type of data, including words, numbers, images, videos, and files. You can use software called a database management system (DBMS) to store, retrieve, and edit data.

2. What is Normalization?

➤ Normalization is the process of organizing data in a database. It includes creating tables and establishing relationships between those tables according to rules designed both to protect the data and to make the database more flexible by eliminating redundancy and inconsistent dependency.

Normalization typically involves several stages or levels, often referred to as normal forms. The most commonly discussed normal forms are:

First Normal Form (1NF), Second Normal Form (2NF), Third Normal Form (3NF), Fourth Normal Form (4NF), Fifth Normal Form (5NF)

3. What is Difference between DBMS and RDBMS?

DBMS:

- Data stored is in file format
- Individual access of data element
- No connection between data
- No support for distributed database
- Data stored is a small quantity
- DBMS support a single user
- The software and hardware requirements are low
- Example: XML, Microsoft Assess

RDBMS:

- Relation database management system.
- Data Stored is in table format.
- Multiple data element is accessible together.
- Data in the form of a table are linked together.
- Support distributed database.
- Data is Stored in large amount.
- RDBMS supports multiple users.
- The software and hardware requirement are higher.
- Example: Oracle, SQL, Server.

4. What is MF Cod Rule of RDBMS Systems?

- ➤ The MF Cod Rule of RDBMS Systems states that for a system to qualify as an RDBMS, it must be able to manage database entirely through the relational capabilities .
- ➤ Rule 0 of the MF Cod Rules states that the system must qualify as relational, as a database, and as a management system.
- For a system to qualify as an RDBMS, that system must use its relational facilities exclusively to manage the database.

5. What do you understand by Data Redundancy?

- ➤ Data redundancy refers to the unnecessary repetition or duplication of data within a database or across different databases or systems.
- ➤ It occurs when the same piece of data is stored in multiple places.
- > This redundancy can lead to several issues:
 - Increased Storage Requirements
 - Inconsistency
 - Update Anomalies
 - Decreased Performance
 - Difficulty in Data Management

6. What is DDL Interpreter?

- ➤ A DDL (Data Definition Language) Interpreter is a component of a Database Management System (DBMS) that processes and executes Data Definition Language commands.
- ➤ DDL commands are used to define and manage the structure of databases and database objects such as tables, indexes, views, and schemas.
- ➤ The primary role of the DDL Interpreter is to translate these commands into internal instructions that the DBMS can understand and execute.

7. What is DML Compiler in SQL?

The Data Manipulation Language, or DML for short, is the group of commands responsible for manipulating data in a database; this generally entails inserting, editing, or deleting rows in SQL tables.

DML statements are typically processed within a DBMS, which involves a combination of components including compilers and interpreters:

- Query Parser
- Query Optimizer
- Execution Engine

8. What is SQL Key Constraints writing an Example of SQL Key Constraints

Constraints are the rules that we can apply on the type of data in a table. That is, we can specify the limit on the type of data that can be stored in a particular column in a table using constraints.

• NOT NULL:

This constraint tells that we cannot store a null value in a column. That is, if a column is specified as NOT NULL then we will not be able to store null in this particular column any more.

• UNIQUE:

This constraint when specified with a column, tells that all the values in the column must be unique. That is, the values in any row of a column must not be repeated.

• PRIMARY KEY:

A primary key is a field which can uniquely identify each row in a table. And this constraint is used to specify a field in a table as primary key.

• FOREIGN KEY:

A Foreign key is a field which can uniquely identify each row in another table. And this constraint is used to specify a field as foreign key.

• CHECK:

This constraint helps to validate the values of a column to meet a particular condition. That is, it helps to ensure that the value stored in a column meets a specific condition.

• DEFAULT:

This constraint specifies a default value for the column when no value is specified by the user.

9. What is save Point? How to create a save Point write a Query?

➤ A save point in SQL is a logical rollback point within a transaction.

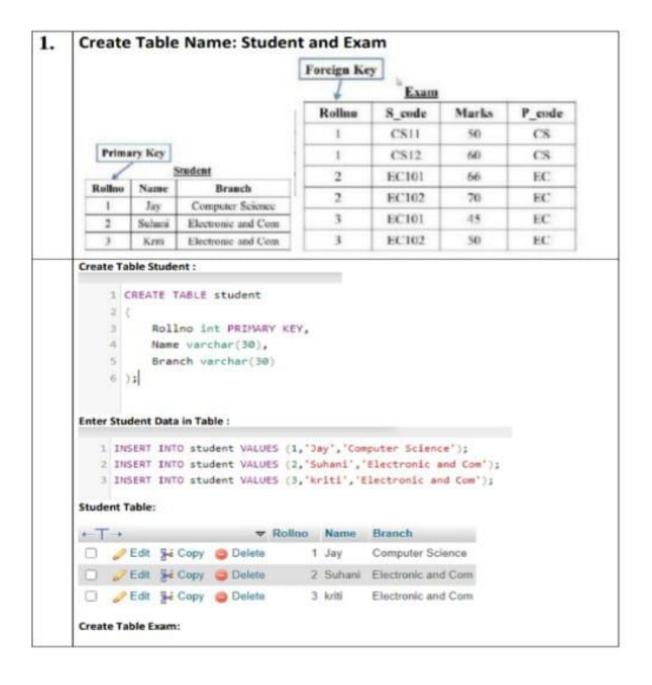

- ➤ It allows you to specify a point in a transaction that you can roll back to without affecting the entire transaction.
- Syntax: 'SAVEPOINT savepoint_name'
- ➤ You can then perform various SQL operations Within the transaction. To roll back to a specific save point use 'ROLLBACK TO save_point_name'.

10. What is trigger and how to create a Trigger in SQL?

- ➤ A trigger in SQL is a special type of stored procedure that automatically executes in response to certain events on a particular table or view in a database. These events can include INSERT, UPDATE, DELETE operations or a combination thereof. Triggers are used to enforce business rules, validate input data, maintain referential integrity, and automate actions based on database events.
- ➤ Example: We are adding tuple to the 'Donors' table that is some Person has donated blood. So we can design a trigger that will automatically add the value of donated blood to the 'blood_record' table.
- ➤ We can define 6 types of triggers for each table:
 - AFTER INSERT: activated after data is inserted into the table.
 - AFTER UPDATE: activated after data in the table is modified.
 - AFTER DELETE: activated after data is deleted/removed from the table.
 - BEFORE INSERT: activated before data is inserted into the table.

- BEFORE UPDATE: activated before data in the table is modified.
- BEFORE DELETE: activated before data is deleted/removed from the table.

SQL QUERIES

```
1 CREATE TABLE Exam
      2 (
      3
          Rollno int,
      4
           5 code varchar(30),
          Marks int,
      5
      6
           P_code varchar(30),
            FOREIGN KEY(Rollno) REFERENCES student(Rollno)
      7
      8 );
     Enter Data in Table :
        1 INSERT INTO exam VALUES(1, 'CS11', S0, 'CS');
        2 INSERT INTO exam VALUES(1, 'C512',60, 'C5');
        3 INSERT INTO exam VALUES(2, 'EC101', 66, 'EC');
        4 INSERT INTO exam VALUES(2, 'EC102', 70, 'EC');
        5 INSERT INTO exam VALUES(3, 'EC101',45, 'EC');
        6 INSERT INTO exam VALUES(3, 'EC102', 50, 'EC');
     Exam Table:
      Rollno S code Marks P code
            1 CS11
                          50 CS
                          60 CS
            1 CS12
            2 EC101
                          66 EC
            2 EC102
                          70 EC
            3 EC101
                          45 EC
            3 EC102
                          50 EC
    Create table given below: Employee and Incentive Table.
2
    Create Table Employee:
       1 CREATE TABLE Employee
       2 (
       3
             Employee_id int PRIMARY KEY,
             First_name varchar(30),
       4
       5
             Last_name varchar(30),
       6
             Salary int,
       7
             Joining date timestamp,
```

Department varchar(30)

8

Enter Data:

33

```
1 INSERT INTO employee VALUES (1, "John", "Abraham", 1000000, '2013-01-01 12:00:00Am", 'Banking');
2 INSERT INTO employee VALUES (2, "Michael", "Claeke", 800000, '2013-01-01 12:00:00Am", 'Insurance");
3 INSERT INTO employee VALUES (3, "Boy", 'Thomas", 700000, '2013-01-01 12:00:00Am", 'Sanking');
4 INSERT INTO employee VALUES (4, "Tom", "Jose", 600000, '2013-01-01 12:00:00Am", 'Insurance');
5 INSERT INTO employee VALUES (5, "Jerry", "Pinto", 650000, '2013-01-01 12:00:00Am", 'Insurance');
6 INSERT INTO employee VALUES (6, "Philip", "Nethow", 750000, '2013-01-01 12:00:00Am", 'Services');
7 INSERT INTO employee VALUES (7, "TestName1", '123", 650000, '2013-01-01 12:00:00Am", 'Services');
8 INSERT INTO employee VALUES (8, "TestName1", 'LnameN", 600000, '2013-01-01 12:00:00Am", 'Insurance');
```

Employee Table:

Employee_id	First_name	Last name	Salary	Joining_date	Department
